

Yield Tree & DIG

Decompose yield. Map dependencies.

— TWO PROPRIETARY BUILDING BLOCKS

CONFIDENTIAL • For internal discussion only

Yield Tree Decomposition (YTD)

WHAT IT IS

Recursive unwrapping of any LP token down to its **primary collateral**.

WHAT IT SOLVES

- Trace every yield source *layer by layer*
- Isolate the **true exposure** under the wrapping
- Distinguish *organic* vs *borrowed* yield
- Quantify **per-leaf risk**

Ex: bbqUSDC → Curve LP → {USDC, crvUSD}
→ RWA collateral.

Recursive unwrap down to underlying assets

DeFi Integration Graph (DIG)

WHAT IT IS

Real-time mapping of every transitive dependency of an *onchain* token. **500+** nodes across **7+** protocols.

WHAT IT SOLVES

- Spot **contagion points** upstream
- Visualize oracles, bridges, multisigs, RWA
- **Alert** on any structural change
- Quantify any protocol's *blast radius*

500+ nodes across 7+ protocols, updated in real time

Why it matters

YTD

See where every basis point of yield comes from.

No black-box yield. Every leaf has a name, a protocol, and a risk.

DIG

See what every position hangs on.

Oracles, bridges, multisigs — anything that can break is in the graph.

YTD $\cap$ DIG

Collateral + contagion decision, at a glance.

One unified view to size, hedge, or exit before the market does.

★ Two tools, one thesis: **yield only matters if you know everything that carries it.**
